1. Document Revisions

0.1	Draft report	12.10.2022
1.0	Final report	19.10.2022

2. Overview

This document presents our findings in reviewed contracts.

2.1. Ackee Blockchain

[Ackee Blockchain](#) is an auditing company based in Prague, Czech Republic, specializing in audits and security assessments. Our mission is to build a stronger blockchain community by sharing knowledge & we run free certification courses [School of Solana](#), [Summer School of Solidity](#) and teach at the Czech Technical University in Prague. Ackee Blockchain is backed by the largest VC fund focused on blockchain and DeFi in Europe, [Rockaway Blockchain Fund](#).

2.2. Audit Methodology

1. Technical specification/documentation - a brief overview of the system is requested from the client and the scope of the audit is defined.
2. Tool-based analysis - deep check with automated Solidity analysis tools and Woke is performed.
3. Manual code review - the code is checked line by line for common vulnerabilities, code duplication, best practices and the code architecture is reviewed.
4. Local deployment + hacking - the contracts are deployed locally and we try to attack the system and break it.
5. Unit and fuzzy testing - run unit tests to ensure that the system works as expected, potentially write missing unit or fuzzy tests.

2.3. Finding classification

A *Severity* rating of each finding is determined as a synthesis of two sub-ratings: *Impact* and *Likelihood*. It ranges from *Informational* to *Critical*.

If we have found a scenario in which an issue is exploitable, it will be assigned an impact rating of *High*, *Medium*, or *Low*, based on the direness of the consequences it has on the system. If we haven't found a way, or the issue is only exploitable given a change in configuration (such as deployment scripts, compiler configuration, use of multi-signature wallets for owners, etc.) or given a change in the codebase, then it will be assigned an impact rating of *Warning* or *Info*.

Low to *High* impact issues also have a *Likelihood*, which measures the probability of exploitability during runtime.

The full definitions are as follows:

Severity

		<i>Likelihood</i>			
		High	Medium	Low	-
<i>Impact</i>	High	Critical	High	Medium	-
	Medium	High	Medium	Medium	-
	Low	Medium	Medium	Low	-
	Warning	-	-	-	Warning
	Info	-	-	-	Info

Table 1. Severity of findings

Impact

- ¥ High - Code that activates the issue will lead to undefined or catastrophic consequences for the system.
- ¥ Medium - Code that activates the issue will result in consequences of serious substance.
- ¥ Low - Code that activates the issue will have outcomes on the system that are either recoverable or don't jeopardize its regular functioning.
- ¥ Warning - The issue cannot be exploited given the current code and/or configuration (such as deployment scripts, compiler configuration, use of multi-signature wallets for owners, etc.), but could be a security vulnerability if these were to change slightly. If we haven't found a way to exploit the issue given the time constraints, it might be marked as a "Warning" or higher, based on our best estimate of whether it is currently exploitable.
- ¥ Info - The issue is on the borderline between code quality and security. Examples include insufficient logging for critical operations. Another example is that the issue would be security-related if code or configuration (see above) was to change.

Likelihood

- ¥ High - The issue is exploitable by virtually anyone under virtually any circumstance.
- ¥ Medium - Exploiting the issue currently requires non-trivial preconditions.
- ¥ Low - Exploiting the issue requires strict preconditions.

2.4. Review team

Members Name	Position
Michal Plevřtil	Lead Auditor
Jan Kalivoda	Auditor
Josef Gattermayer, Ph.D.	Audit Supervisor

2.5. Disclaimer

We've put our best effort to find all vulnerabilities in the system, however our findings shouldn't be considered as a complete list of all existing issues. The statements made in this document should not be interpreted as investment or legal advice, nor should its authors be held accountable for decisions made based on them.

3. Executive Summary

The first objective of the audit is a part of the Axelar Utils repository, with a custom implementation of a const address contract deployer and helper libraries to convert between string and address and between string and bytes32. The second objective is Squid Router which allows users to send tokens through the Axelar Gateway and optionally execute arbitrary operations (external calls) on both the source and destination chains.

Revision 1

Axelar engaged Ackee Blockchain to perform a security review of the Axelar Utils and Squid Router implementation with a total time donation of 5 engineering days in a period between October 3 and October 7, 2022 with Michal Pleveřtil as the lead auditor.

The audit was performed on two repositories with the following commits and files.

¥ [Axelar Utils](#) - 726020f

! contracts/ConstAddressDeployer.sol

! contracts/StringAddressUtils.sol

! contracts/StringBytesUtils.sol

¥ A private repository - cdd406a

! packages/squidswap-contracts/contracts/RoledPausable.sol

! packages/squidswap-contracts/contracts/SquidMulticall.sol

! packages/squidswap-contracts/contracts/SquidRouterProxy.sol

! packages/squidswap-contracts/contracts/SquidRouter.sol

We began our review by using static analysis tools, namely [Woke](#) and [Slither](#).

Outputs from [Woke](#) are enclosed in [Appendix C](#). Then we implemented fuzz tests using [Woke](#) and [Brownie](#) to discover potential vulnerabilities. Sources of fuzz tests are available in [Appendix D](#).

We took a deep dive into the logic of the contracts. During the review, we paid special attention to:

- ¥ contracts are not susceptible to re-entrancy attacks,
- ¥ users of the contracts cannot lose their funds,
- ¥ helper and library functions work for all possible inputs,
- ¥ input data are properly validated.

Our review resulted in 20 findings, ranging from Info to High severity.

Ackee Blockchain recommends Axelar and Squid:

- ¥ reconsider the current architecture being too generic allowing loss of user funds with improperly crafted input data,
- ¥ not to rely only on the off-chain implementation and add data validation to the contracts,
- ¥ add NatSpec comments to the code,
- ¥ address all other reported issues.

See the full report in chapter [Revision 1](#).

4. Summary of Findings

The following table summarizes the findings we identified during our review.

Unless overridden for purposes of readability, each finding contains:

¥ a *Description*,

¥ an *Exploit scenario*,

¥ a *Recommendation* and if applicable

¥ a *Solution*.

Many times, there might be multiple ways to solve or alleviate the issue, with varying requirements in terms of the necessary changes to the codebase. In that case, we will try to enumerate them all, making clear which solves the underlying issue better (albeit possibly only with architectural changes) than others.

	Severity	Impact	Likelihood
H1: fundAndRunMulticall is not pausable	High	High	Medium
M1: Missing CallType validation	Medium	High	Low
M2: Missing isContract check in SquidMulticall	Medium	High	Low
M3: Memory address overflow in setCallDataParameter	Medium	High	Low

Table 2. Table of Findings

5. Report revision 1.0

The first revision of the audit report.

System Overview

This section contains an outline of the audited contracts. Note that this is meant for understandability purposes and does not replace project documentation.

Contracts

Contracts we find important for better understanding are described in the following section.

SquidMulticall

SquidMulticall is a contract that allows executing multiple calls to other contracts in a single transaction. In a typical scenario, the external calls perform ERC-20 token purchases, swaps and transfers. There are multiple external call types to support these operations.

SquidRouter

SquidRouter optionally performs a user-defined multicall on a source chain (through the [SquidMulticall](#) contract), sends token through the Axelar Gateway, and then optionally performs another user-defined multicall on a destination chain. It is also supported to perform a multicall without sending tokens through the Axelar Gateway.

SquidRouterProxy

SquidRouterProxy suits as a proxy contract for the [SquidRouter](#) contract. This allows the [SquidRouter](#) contract to be upgraded with a new implementation while keeping the same address.

Actors

Pauser

A pauser of the [SquidRouter](#) contract can pause all public functions of the contract. This is useful for emergency situations, such as a bug in the contract or a security issue. A pauser can be changed using a two-step transfer process.

Owner

An owner of the [SquidRouterProxy](#) contract can deploy a new implementation of the [SquidRouter](#) contract. This effectively also changes the pauser of the [SquidRouter](#) contract to the owner.

User

A user can call the [SquidRouter](#) contract to perform an Axelar Gateway bridge operation with optional multicalls on both source and destination chains. A user can also perform a multicall without sending tokens through the Axelar Gateway.

Trust model

Users have to trust the [Owner](#) of the [SquidRouterProxy](#) contract to not deploy a malicious implementation of the [SquidRouter](#) contract. Users also have to trust the tokens they own and the tokens they want to be purchased/swapped in the [SquidMulticall](#) contract. Users have to trust any off-chain service that they use to interact with the [SquidRouter](#) contract. More specifically, users have to trust the off-chain implementation that generates commands (calls) for the [SquidMulticall](#) contract.

H1: `fundAndRunMul ti cal l` is not pausable

High severity issue

Impact:	High	Likelihood:	Medium
Target:	/packages/squidswap-contracts/contracts/SquidRouter.sol	Type:	Logic error

Listing 1. Excerpt from /packages/squidswap-contracts/contracts/SquidRouter.sol #L100-L104[SquidRouter.fundAndRunMul ti cal l]

```
100     function fundAndRunMul ti cal l (  
101         address token,  
102         uint256 amount,  
103         ISquidMul ti cal l. Cal l [] memory cal ls  
104     ) public payable {
```

Description

From the documentation provided, all external and public functions should be pausable to be able to stop the contract in case of an emergency. However, the `fundAndRunMul ti cal l` function is not pausable.

Exploit scenario

A serious vulnerability in the `SquidMul ti cal l` is discovered. Before the vulnerability is fixed, anyone can call the `fundAndRunMul ti cal l` function because it is not pausable.

Recommendation

Either add the `whenNotPaused` modifier to the `fundAndRunMul ti cal l` function or clarify in the documentation that this function is not pausable.

[Go back to Findings Summary](#)

M1: Missing `call.callType` validation

Medium severity issue

Impact:	High	Likelihood:	Low
Target:	/packages/squidswap-contracts/contracts/SquidMulticall.sol	Type:	Data validation

Listing 2. Excerpt from /packages/squidswap-contracts/contracts/SquidMulticall.sol #L21-L31[SquidMulticall.run]

```

21         if (call.callType == CallType.FullTokenBalance) {
22             (address token, uint256 amountParameterPosition) =
23             abi.decode(call.payload, (address, uint256));
24             uint256 amount = IERC20(token).balanceOf(address(this));
25             _setCallDataParameter(call.callData,
26             amountParameterPosition, amount);
27         } else if (call.callType == CallType.FullNativeBalance) {
28             call.value = address(this).balance;
29         } else if (call.callType == CallType.CollectTokenBalance) {
30             address token = abi.decode(call.payload, (address));
31             _safeTransferFrom(token, msg.sender,
32             IERC20(token).balanceOf(msg.sender));
33             continue;
34         }

```

Description

The `run` function does not handle the case where `call.callType` is not one of the expected values.

Exploit scenario

A new `callType` is implemented with the documentation being updated before the `SquidRouter` contract is upgraded. As a result, users send transactions

with the new `cal I Type` value, leading to unexpected behavior.

Recommendation

Revert the transaction if `cal I . cal I Type` is not one of the expected values.

[Go back to Findings Summary](#)

M2: Missing `isContract` check in `SquidMultiCall`

Medium severity issue

Impact:	High	Likelihood:	Low
Target:	/packages/squidswap-contracts/contracts/SquidMultiCall.sol	Type:	Data validation

Listing 3. Excerpt from /packages/squidswap-contracts/contracts/SquidMultiCall.sol #L33-L34[SquidMultiCall.run]

```

33         (bool success, bytes memory data) = call.target.call{value:
    Ê call.value}(call.callData);
34         if (!success) revert CallFailed(i, data);
  
```

Description

The `success` variable will be set to `true` even if `call.target` is not a contract.

Exploit scenario

A user mistypes an address of a decentralized exchange where he wanted to purchase ERC-20 tokens. Ether that would have been used to purchase the tokens is sent to a different account than expected. The transaction does not revert, resulting in a loss of Ether. Before the user manages to call a transaction requesting the Ether back, another user calls the `SquidMultiCall` contract and receives the leftover Ether.

Recommendation

Add a boolean flag to the `Call` struct indicating whether the target is a contract. If the flag is set to `true`, check that `call.target` is a contract before performing the external call.

[Go back to Findings Summary](#)

M3: Memory address overflow in `_setCallDataParameter`

Medium severity issue

Impact:	High	Likelihood:	Low
Target:	/packages/squidswap-contracts/contracts/SquidMulticall.sol	Type:	Data validation

Listing 4. Excerpt from /packages/squidswap-contracts/contracts/SquidMulticall.sol #L56-L65[`SquidMulticall._setCallDataParameter`]

```

56     function _setCallDataParameter(
57         bytes memory callData,
58         uint256 parameterPosition,
59         uint256 value
60     ) private pure {
61         assembly {
62             // 36 bytes shift because 32 for prefix + 4 for selector
63             mstore(add(callData, add(36, mul(parameterPosition, 32))),
64                 value)
65         }

```

Description

The `_setCallDataParameter` function allows overwriting the `callData` variable at a given position with a 256-bit value. The function does not check if the given position is within the bounds of the `callData` variable. Given the fact that the operation is performed in an inline assembly block, this can lead to a memory address overflow and overwrite arbitrary memory locations.

Among vulnerable objects in memory are:

- ¥ selector and prefix parts of the `calldata` variable,
- ¥ address of the next external call to be performed in the `run` function,
- ¥ free memory pointer at memory location `0x40`.

Overwriting the free memory pointer can lead to memory corruption and malformation of any data to be stored in memory.

Exploit scenario

A user encodes `-1` as a value of the `parameterPosition` parameter. Because the data are encoded using the ABI encoding and interpreted as `uint256`, the `mstore` instruction is evaluated as:

```
mstore(add(calldata, add(36, mul(2 ** 256 - 1, 32))), value)
```

which is equal to:

```
mstore(add(calldata, 4), value)
```

This effectively overwrites both the prefix part (except the first four bytes) and the selector part of the `calldata` variable, leading to unexpected behavior.

Recommendation

Add a check that the given position is within the bounds of the `calldata` variable and does not overwrite the prefix and selector parts.

[Go back to Findings Summary](#)

M4: Multicall implementation being too generic

Medium severity issue

Impact:	High	Likelihood:	Low
Target:	/packages/squidswap-contracts/contracts/SquidMulticall.sol	Type:	Data validation

Listing 5. Excerpt from /packages/squidswap-
contracts/contracts/SquidMultiCall.sol #L12-L42[SquidMultiCall.run]

```

12     function run(Call[] calldata calls) external payable {
13         // Prevents reentrancy
14         if (isRunning) revert AlreadyRunning();
15         isRunning = true;
16
17         uint256 length = calls.length;
18         for (uint256 i = 0; i < length; ) {
19             Call memory call = calls[i];
20
21             if (call.callType == CallType.FullTokenBalance) {
22                 (address token, uint256 amountParameterPosition) =
23                 Ê abi.decode(call.payload, (address, uint256));
24                 uint256 amount = IERC20(token).balanceOf(address(this));
25                 _setCallDataParameter(call.callData,
26                 Ê amountParameterPosition, amount);
27             } else if (call.callType == CallType.FullNativeBalance) {
28                 call.value = address(this).balance;
29             } else if (call.callType == CallType.CollectTokenBalance) {
30                 address token = abi.decode(call.payload, (address));
31                 _safeTransferFrom(token, msg.sender,
32                 Ê IERC20(token).balanceOf(msg.sender));
33                 continue;
34             }
35
36             (bool success, bytes memory data) = call.target.call{value:
37             Ê call.value}(call.callData);
38             if (!success) revert CallFailed(i, data);
39
40             unchecked {
41                 ++i;
42             }
43         }
44         isRunning = false;
45     }

```

Description

Given described a typical scenario in the [documentation](#), the `SquidMultiCall` contract implementation is too generic and does not perform any checks to ensure that the user cannot lose funds. Especially, it is not verified that:

- ¥ Ether (or the native currency) remaining after all calls are executed is returned to the caller (i.e. the `SquidMultiCall` contract does not hold any Ether at the end of the transaction),
- ¥ all tokens are sent to the user or the `SquidRouter` contract (i.e. the `SquidMultiCall` contract does not hold any tokens at the end of the transaction),
- ¥ up to one type of ERC-20 token is sent to the `SquidRouter` contract and this type of token is the same as the token type to be sent through the Axelar Gateway (i.e. the `SquidRouter` contract does not hold any tokens at the end of the transaction).

Exploit scenario

Due to faulty off-chain implementation, empty `calls` variable is passed to the `SquidMultiCall.run` function. As a result, any tokens or Ether sent to the `SquidMultiCall` contract (via the `SquidRouter.fundAndRunMultiCall` function) are left in the contract. Before the user manages to call a transaction requesting the Ether or tokens back, another user calls the `SquidMultiCall` contract and extracts the leftover Ether or tokens.

Recommendation

It is strongly advised to reconsider the current implementation of the `SquidMultiCall` contract. If an architectural change is not an option, add safety checks for the invariants described in the previous paragraph and fix the following issues:

- ¥ [M1: Missing `Call`.`call` Type validation](#),
- ¥ [M2: Missing `isContract` check in `SquidMultiCall`](#),
- ¥ [M3: Memory address overflow in `setCallDataParameter`](#).

[Go back to Findings Summary](#)

M5: Re-entrancy in SquidRouter

Medium severity issue

Impact:	Medium	Likelihood:	Low
Target:	/packages/squidswap-contracts/contracts/SquidRouter.sol	Type:	Re-entrancy

Listing 6. Excerpt from /packages/squidswap-contracts/contracts//SquidRouter.sol #L72-L82[SquidRouter.callBridgeCall]

```
72     function callBridgeCall(  
73         address token,  
74         uint256 amount,  
75         string calldata destinationChain,  
76         string calldata bridgedTokenSymbol,  
77         ISquidMultiCall.Call[] calldata sourceCalls,  
78         ISquidMultiCall.Call[] calldata destinationCalls,  
79         address refundRecipient,  
80         bool enableForecall  
81     ) external payable whenNotPaused {  
82         fundAndRunMultiCall(token, amount, sourceCalls);
```

Listing 7. Excerpt from /packages/squidswap-contracts/contracts//SquidRouter.sol #L41-L51[SquidRouter.bridgeCall]

```

41     function bridgeCall(
42         string calldata destinationChain,
43         string calldata bridgedTokenSymbol,
44         uint256 amount,
45         ISquidMulticall.Calldata[] calldata calls,
46         address refundRecipient,
47         bool enableForecall
48     ) external payable whenNotPaused {
49         address bridgedTokenAddress =
50             gateway.tokenAddresses(bridgedTokenSymbol);
51         _safeTransferFrom(bridgedTokenAddress, msg.sender, amount);

```

Listing 8. Excerpt from /packages/squidswap-contracts/contracts//SquidRouter.sol #L100-L114[SquidRouter.fundAndRunMulticall]

```

100    function fundAndRunMulticall(
101        address token,
102        uint256 amount,
103        ISquidMulticall.Calldata[] memory calls
104    ) public payable {
105        uint256 valueToSend;
106
107        if (token == address(0)) {
108            valueToSend = amount;
109        } else {
110            _transferTokenToMulticall(token, amount);
111        }
112
113        squidMulticall.run{value: valueToSend}(calls);
114    }

```

Description

Assuming that tokens a user owns and/or swaps in the `SquidMulticall`

contract cannot be considered trusted, re-entrancy in the **SquidRouter** contract opens up the possibility to extract Ether (or the native currency) that would be otherwise used as an Axelar gateway fee.

Exploit scenario

The re-entrancy is possible in two different scenarios:

- ¥ a user calls **callBridgeCall** with a non-zero malicious **token** address and Ether to be paid to the Axelar Gas Service,
- ¥ **_transferTokenToMulticall** called from **fundAndRunMulticall** performs an external call to the malicious **token** address,
- ¥ **token** calls **fundAndRunMulticall** with zero **token** address, **amount** set to **address(msg.sender).balance** and **calls** saying to transfer all Ether to the malicious token,
- ¥ as a side effect, it is not paid to the Axelar Gas Service, resulting in tokens sent to the Axelar Gateway being stuck until the user pays the fee on the destination chain.

The second scenario is as follows:

- ¥ a user calls **bridgeCall** with Ether to be paid to the Axelar Gas Service,
- ¥ **_safeTransferFrom** called from **bridgeCall** performs an external call to the malicious **bridgedTokenAddress** address,
- ¥ the rest of the scenario is the same as above.

Recommendation

Add re-entrancy guards to the **SquidRouter** contract.

[Go back to Findings Summary](#)

M6: Missing refundRecipient validation

Medium severity issue

Impact:	High	Likelihood:	Low
Target:	/packages/squidswap-contracts/contracts/SquidRouter.sol	Type:	Data validation

Description

Functions `bridgeCall` and `callBridgeCall` accept `refundRecipient` as a parameter. However, the value of the parameter is not validated. Given that the `refundRecipient` address is used to transfer funds in case of a revert in the `SquidMulticall` contract on the destination chain, lack of validation may lead to loss of funds.

Exploit scenario

Due to faulty off-chain implementation, the default value (which is the zero address) is passed to the `bridgeCall` function. The user-defined multicall on the destination chain fails and the bridged tokens are transferred to the zero address.

Recommendation

Add a check that the `refundRecipient` parameter is not the zero address.

[Go back to Findings Summary](#)

M7: Missing `destinationChain` validation

Medium severity issue

Impact:	High	Likelihood:	Low
Target:	/packages/squidswap-contracts/contracts/SquidRouter.sol	Type:	Data validation

Description

Functions `bridgeCall`, `callBridge` and `callBridgeCall` accept `destinationChain` as a parameter. However, the value of the parameter is not validated. Additionally, Axelar `sendToken` and `callContractWithToken` functions do not perform the validation neither. This may lead to loss of funds if the `destinationChain` parameter is set to an invalid value.

Exploit scenario

Due to faulty off-chain implementation, the `destinationChain` parameter is set to an invalid value. Because Axelar does not perform any validation of the `destinationChain` parameter neither, the tokens sent to the Axelar gateway are burned on the source chain. The tokens are lost as Axelar does not support refunds of the tokens sent to an invalid destination chain.

Recommendation

Add validation for `destinationChain` parameters to all functions concerned to avoid potential loss of user funds. Axelar [documents](#) all supported chain names.

[Go back to Findings Summary](#)

W1: Missing validation of the 0x prefix in string addresses

Impact:	Warning	Likelihood:	N/A
Target:	Axelar Utils /contracts/StringAddress Utils.sol	Type:	Data validation

*Listing 9. Excerpt from [Axelar](#)
[Utils](#)/contracts/StringAddressUtils.sol #L6-
L11[StringToAddress.toAddress]*

```
6     function toAddress(string memory _a) internal pure returns (address)
7     {
8         bytes memory tmp = bytes(_a);
9         if (tmp.length != 42) return address(0);
10        uint160 iaddr = 0;
11        uint8 b;
12        for (uint256 i = 2; i < 42; i++) {
```

Description

It is not checked whether the string passed to the `toAddress` function starts with the 0x prefix.

Recommendation

Add a check to ensure that the string starts with the 0x prefix.

[Go back to Findings Summary](#)

W2: Use of **sol c** optimizer

Impact:	Warning	Likelihood:	N/A
Target:	**/*.sol	Type:	Compiler configuration

Description

Both audited projects use the **sol c** optimizer. Enabling the optimizer [may lead to unexpected bugs](#) and should be used with caution. More significantly, both projects can be compiled with the latest version of the **sol c** compiler that may be a subject to new undiscovered bugs.

The Solidity compiler was audited in November 2018, and the audit [concluded](#) that the optimizer may not be safe to use in production.

Recommendation

Until the **sol c** optimizer becomes more stable and undergoes more stringent security analysis, opt-out using it. This will ensure that the contracts are resilient to any existing bugs in the optimizer.

[Go back to Findings Summary](#)

W3: Address helper functions not respecting EIP-55

Impact:	Warning	Likelihood:	N/A
Target:	Axelar Utils /contracts/StringAddress Utils.sol	Type:	Standards violation

Description

[EIP-55](#) defines a checksummed address format using mixed case letters to prevent mistyping of addresses. The functions `toAddress` and `toString` in `StringAddressUtils` do not respect this standard.

Recommendation

It should be either clearly stated in the documentation and NatSpec documentation strings that the functions do not respect [EIP-55](#) or the functions should implement both [EIP-55](#) checksum verification and generation.

[Go back to Findings Summary](#)

W4: **SquidRouter** pausable can be bypassed

Impact:	Warning	Likelihood:	N/A
Target:	/packages/squidswap-contracts/contracts/SquidRouter.sol	Type:	Logic error

Description

Given that the **SquidRouter** contract uses upgradeable proxies, functions paused through the proxy contract can still be executed by calling the function directly on the implementation contract. Furthermore, the pauser address (the address that can pause the contract) can be different when calling the function through the proxy contract and when calling the function directly on the implementation contract.

Recommendation

Either ensure that the fact that the **SquidRouter** pause ability can be bypassed is an expected behavior, or when pausing the **SquidRouter** contract, make sure to call the **pause** function both on the proxy contract and on the implementation contract.

[Go back to Findings Summary](#)

I1: Unnecessary `abi.encodePacked`

Impact:	Info	Likelihood:	N/A
Target:	Axelar Utils /contracts/StringBytesUtils.sol	Type:	Gas optimization

Listing 10. Excerpt from [Axelar](#)

[Utils](#)/contracts/StringBytesUtils.sol #L15-L19[*StringToBytes32.toBytes32*]

```
15      uint256 stringNumber = uint256(bytes32(stringBytes));
16
17      // Storing string length as the last byte of the data
18      stringNumber |= 0xff & stringBytes.length;
19      return bytes32(abi.encodePacked(stringNumber));
```

Description

`uint256` can be directly converted to `bytes32` without using `abi.encodePacked`.

Recommendation

Remove the `abi.encodePacked` call.

[Go back to Findings Summary](#)

I2: Multiple calls to `pendingPauser`

Impact:	Info	Likelihood:	N/A
Target:	/packages/squidswap-contracts/contracts/RoledPausable.sol	Type:	Gas optimization

Listing 11. Excerpt from /packages/squidswap-contracts/contracts/RoledPausable.sol #L33-L37[RoledPausable.acceptPauser]

```
33     function acceptPauser() external {
34         if (msg.sender != pendingPauser()) revert NotPendingPauser();
35         _setPauser(pendingPauser());
36         PENDING_PAUSER_SLOT.setAddress(address(0));
37     }
```

Description

The `pendingPauser` function is called twice in the `acceptPauser` function, but there is no possibility of the pending pauser being set to a different address between these two calls.

Recommendation

The second call to `pendingPauser` can be replaced by `msg.sender`.

[Go back to Findings Summary](#)

I3: Bytes length accessed in a for loop condition

Impact:	Info	Likelihood:	N/A
Target:	Axelar Utils /contracts/StringAddress Utils.sol	Type:	Gas optimization

Listing 12. Excerpt from [Axelar](#)

[Utils](#)/contracts/StringAddressUtils.sol #L25-

L35[AddressToString.toString]

```

25     bytes memory data = abi.encodePacked(a);
26     bytes memory characters = '0123456789abcdef';
27     bytes memory byteString = new bytes(2 + data.length * 2);
28
29     byteString[0] = '0';
30     byteString[1] = 'x';
31
32     for (uint256 i; i < data.length; ++i) {
33         byteString[2 + i * 2] = characters[uint256(uint8(data[i] >>
34     Ê 4))];
34         byteString[3 + i * 2] = characters[uint256(uint8(data[i] &
35     Ê 0x0f))];
35     }
```

Description

`data.length` is accessed in every iteration of the for loop. This is not necessary, as the length of the `data` variable is not modified in the loop.

Recommendation

`data.length` should be stored in a local variable before the loop, and the local variable should be used in the loop condition.

[Go back to Findings Summary](#)

I4: Inconsistent for loop incrementation

Impact:	Info	Likelihood:	N/A
Target:	Axelar Utils /contracts/StringAddress Utils.sol	Type:	Code style

*Listing 13. Excerpt from [Axelar](#)
[Utils](#)/contracts/StringAddressUtils.sol #L11-
L11[StringToAddress. toAddress]*

```
11      for (uint256 i = 2; i < 42; i++) {
```

*Listing 14. Excerpt from [Axelar](#)
[Utils](#)/contracts/StringAddressUtils.sol #L32-
L32[AddressToString. toString]*

```
32      for (uint256 i; i < data.length; ++i) {
```

Description

The loop `i` variable is incremented in the `AddressToString. toString` function using the post-fix syntax `i++`, while it is incremented using the pre-fix syntax `++i` in the `StringToAddress. toAddress` function.

Recommendation

Libraries in the same project should be consistent in their coding style.

[Go back to Findings Summary](#)

I5: Address code length can be checked before a call

Impact:	Info	Likelihood:	N/A
Target:	/packages/squidswap-contracts/contracts/{SquidMulticall.sol, SquidRouter.sol}	Type:	Gas optimization

Listing 15. Excerpt from /packages/squidswap-contracts/contracts/SquidMulticall.sol #L49-L53[SquidMulticall._safeTransferFrom]

```

49         (bool success, bytes memory returnData) = token.call(
50             abi.encodeWithSelector(IERC20.transferFrom.selector, from,
51             address(this), amount)
52         );
53         bool transferred = success && (returnData.length == uint256(0)
54         || abi.decode(returnData, (bool)));
55         if (!transferred || token.code.length == 0) revert
56         TransferFailed();

```

Listing 16. Excerpt from /packages/squidswap-contracts/contracts/SquidRouter.sol #L188-L192[SquidRouter._transferTokenToMulticall]

```

188         (bool success, bytes memory returnData) = token.call(
189             abi.encodeWithSelector(IERC20.transferFrom.selector,
190             msg.sender, address(squidMulticall), amount)
191         );
192         bool transferred = success && (returnData.length == uint256(0)
193         || abi.decode(returnData, (bool)));
194         if (!transferred || token.code.length == 0) revert
195         TransferFailed();

```

Description

The `token.code.length == 0` check can be performed before the actual call reducing the gas cost of the call in case `token` is not a contract.

Recommendation

Check the address code length before the call.

[Go back to Findings Summary](#)

I6: For loop variable can be incremented in an unchecked block

Impact:	Info	Likelihood:	N/A
Target:	Axelar Utils /contracts/StringAddress Utils.sol	Type:	Gas optimization

*Listing 17. Excerpt from [Axelar](#)
[Utils](#)/contracts/StringAddressUtils.sol #L11-
L11[StringToAddress. toAddress]*

```
11      for (uint256 i = 2; i < 42; i++) {
```

*Listing 18. Excerpt from [Axelar](#)
[Utils](#)/contracts/StringAddressUtils.sol #L32-
L32[AddressToString. toString]*

```
32      for (uint256 i; i < data.length; ++i) {
```

Description

Given the fact that library functions can be called many times in a single transaction, it is important to minimize the gas cost of each call. In this case, the for loop `i` variable can be incremented in an unchecked block to save gas.

Recommendation

Consider incrementing the for loop `i` variable in an unchecked block to save gas.

[Go back to Findings Summary](#)

I7: Missing NatSpec documentation

Impact:	Info	Likelihood:	N/A
Target:	**/*.sol	Type:	Documentation

Description

Both audited projects lack NatSpec documentation comments that are helpful for developers to understand the code.

Recommendation

Add NatSpec documentation to the source code, especially to public/external functions and state variables and libraries that are usually intended to be used by other contracts.

[Go back to Findings Summary](#)

I8: Inconsistent behavior: Revert vs return default

Impact:	Info	Likelihood:	N/A
Target:	Axelar Utils /contracts/{StringAddressUtils.sol, StringBytesUtils.sol}	Type:	Code style

Listing 19. Excerpt from [Axelar](#)

[Utils](#)/contracts/StringAddressUtils.sol #L8-L8[StringToAddress.toAddress]

```
8      if (tmp.length != 42) return address(0);
```

Listing 20. Excerpt from [Axelar](#)

[Utils](#)/contracts/StringBytesUtils.sol #L13-L13[StringToBytes32.toBytes32]

```
13      if (stringBytes.length == 0 || stringBytes.length > 31) revert
    Ê InvalidStringLength();
```

Description

The function `toAddress` returns the zero address if the string is not a valid address while the function `toBytes32` reverts if the string cannot be stored in a `bytes32` variable. This behavior should be consistent across the libraries.

Recommendation

Revert the transaction if the input string of the `toAddress` function cannot be converted to a valid address.

Appendix A: How to cite

Please cite this document as:

[Ackee Blockchain](#), Axelar: Utils & Squid Router, 19.10.2022.

Appendix B: Glossary of terms

The following terms might be used throughout the document:

Superclass/Ancessor of C

A contract that C inherits/derives from.

Subclass/Child of C

A contract that inherits/derives from C.

Syntactic contract

A Solidity contract. May have an inheritance chain, and may be deployed.

Deployed contract

An EVM account with non-zero code. If its source was written in Solidity, it was created through at least one syntactic contract. If that contract had superclasses (parents), it would be composed of multiple syntactic contracts.

Init/initialization function

A non-constructor function that serves as an initializer. Often used in upgradeable contracts.

External entrypoint

A `public` or `external` function.

Public/Publicly-accessible function/entrypoint

An `external` or `public` function that can be successfully executed by any network account.

Mutating function

A non-`view` and non-`pure` function.

Appendix C: Woke outputs

This appendix shows the outputs from the [Woke](#) tool.

C.1. Detectors

[Woke](#) did not detect any issues in the scoped contracts in the [Axelar Utils](#) repository.

The following image lists detections for the contracts in the second audited (private) repository. Some reported detections resulted in the [M5: Re-entrancy in SquidRouter](#) issue. The rest of the detections were evaluated as false positives.

C.2. Graphs

The following graphs were used during the analysis.

Figure 1. Inheritance graph of the SquidRouter contract

Figure 2. Control flow graph of the SquidMultiCall.run function

Appendix D: Fuzz test sources

This appendix shows the fuzz tests used to verify the implementation of the provided contracts. All tests passed successfully.

D.1. ConstAddressDeployer fuzz test

```
import brownie
